### ABSTRACT

The present investigation was undertaken with the objectives to assess the gene action and magnitude and effects of combining ability of 35 hybrids resulted from Line x Tester mating design with seven lines and five testers and the standard check (GHB 558). The analysis of variance for parents and hybrids was highly significant for all traits indicated the existence of appreciable amount of genetic variability in the experimental material. The magnitude of sca variances was higher than the gca variances for all the characters. This indicated non-additive gene action in the inheritance of these traits. The female ICMA 96222 showed good general combing ability for different characters. The cross ICMA 06777 x 18805 R and ICMA 96222 x 18488 R had good x average combiner parents and good x good combiner parents respectively, high per se performance and positive specific combining ability effect for different characters including grain yield.

Key Words: Pear millet, L x T design, combining ability, GCA, SCA.

## INTRODUCTION

Pearl millet [*Pennisetum glaucum* (L.) R. Br.] (also known under synonyms: *P. americanum* (L.) Leeke or *P. typhoides* (Burm.) Stapf and C.E. Hubb.) is an important millet crop of traditional farming systems in tropical and subtropical Asia and sub-Saharan Africa. It was introduced to India about 2000 B.C. [1]. Pearl millet is the fourth most important cereal crop in India, after rice, wheat and sorghum, where it is widely grown in the states of Rajasthan, Maharashtra, Gujarat and Haryana where the food security of the poorest population depends vastly on pearl millet production. It contains adequate amount of essential amino acids such as tryptophan, threonine, arginine, and lysine. It is used as a feed, fodder, construction material and even its potential as a source of biofuel is being explored [16].

Discovery of A1 cytoplasmic-nuclear male sterility (CMS) at Tifton, Georgia, USA [4] initiated the era of hybrid cultivar development in pearl millet [*Pennisetum glaucum* (L). R. Br.], which led to the release of the first grain hybrid in India in 1965 [2]. Since then hundreds of commercial hybrids have been developed and released or commercialized. Hanna [7] identified an A4 CMS system at Tifton, Georgia, USA in a wild grassy *Pennisetum glaucum* (L.) R. Br. subsp. *monodii* (Maire) Brunken. Also, an A5 CMS system was identified in a pearl millet gene pool. Among the various CMS systems reported so far, A4 and A5 CMS systems were found to have the most stable male sterility [14].

Since yield has low heritability, direct selection for yield is not sufficiently effective. So indirect selection for yield has to be done in the light of gene action, by selection of yield contributing traits and with the selection of yield traits. The combining ability studies provide useful information regarding the selection of suitable parents for effective hybridization programme and at the same time elucidates the nature and

#### Krishnan et al

magnitude of gene action. In order to proceed with any breeding programme, the breeder has to know about the gene action and the genetic architecture of population. Since, the nature of gene action varies with genetic architecture of population involved in hybridization, it is necessary to evaluate the parents for their combining ability. Evaluation of crosses and identification of the superior cross combinations (combining ability) for yield and quality traits essential for effective manipulation through hybrid breeding.

## MATERIAL AND METHODS

The experimental material consisted of seven maintainer lines used as female lines (ICMA -06777, ICMA -07777, ICMA-96222, ICMA-97111, ICMA-98444, ICMA-04999 and ICMA-05444) and five restorer lines used as testers (J18488-R, 18587-R, 18805–R, 17369-R and 17548-R), crossed in a Line x Tester mating design. The resultant 35 hybrids along with their 12 parents with check GHB-558 were evaluated in Randomized Block Design with three replications at Centre for Crop Improvement, S. D. Agricultural University, Sardarkrushinagar-385 506 (Gujarat) during summer 2016- 2017. The observations were recorded on five randomly selected competitive plants of each genotype in each replication for various characters *i.e.* days to flowering, days to maturity, plant height (cm), number of effective tillers per plant, ear head length(cm), ear head girth(mm), test weight(g), grain yield per plant(g) and harvest index(%). Days to flowering (DF) on the basis of 50% plants of each genotype flowered, days to maturity (DM) on the basis of 80% plants of each genotype matured were recorded. The replication wise mean values were used in statistical analysis. The data were subjected to analysis of variance as per the procedure suggested by Sukhatme and Amble [15]. The combining ability analysis was performed for a Line x Tester matting design as per the method suggested by Kempthorne [9].

## **RESULTS AND DISCUSSION**

The analysis of variance depicting mean squares due to genotypes were highly significant for all the characters are presented in Table 1. Further, partitioning of the genotypes variance into parents, hybrids and parents vs. hybrids revealed that the parents as well as hybrids exhibited significant differences for all the traits. This indicated the existence of appreciable amount of genetic variability in the experimental material.

Source of variation	d.f	Days to flowering	Days to maturity	Plant height (cm)	No. of effective tillers per plant	Ear head length (cm)	Ear head girth(mm)	Test weight (g)	Grain yield per plant(g)	Harvest index (%)

Table 1: Analysis of variance (Mean square) for parents and hybrids for seed yield and its component characters in pearl millet

\*, \*\* Significant at P=0.05 and P=0.01 levels respectively.

The mean squares obtained in analysis of variance for combining ability and estimated components of genetic variance for various characters are presented in Table 2.

The result revealed that the mean squares due to females were highly significant for days to flowering, days to maturity, ear head length, ear head girth, test weight and harvest index. This indicated significant contribution of females towards general combining ability variance component for these traits. The hybrids exhibited significant negative general combining ability effects were also a good combiner for early maturity. The results were in accordance with Gill *et al.* [6] and Chavan and Nerkar [5].

The mean squares due to males were significant for days to maturity, ear head length, ear head girth, test weight and grain yield per plant. This indicated the importance of males for their contribution towards

#### Krishnan et al

general combining ability variance components. The line × tester mean squares exhibited significance for all plant traits. The ratio of  $\sigma_{gca}^2 / \sigma_{sca}^2$  was less than unity for all the characters under study (Table 2). This suggested greater role of non-additive genetic variance in the inheritance of all the traits under study. Among parents, ICMA 07777, ICMA 96222 and 18488 R were good general combiner for grain yield per plant, plant height, number of effective tillers per plant. The female ICMA 96222 was found as good general combiner for characters like grain yield per plant, days to flowering, days to maturity, test weight, harvest index. While ICMA 07777 was good combiner for days to flowering, ear head girth and test weight and harvest index. Among males, 18488-R was found as a good combiner for grain yield per plant, ear head girth and test weight (Table 3).

\*, \*\* Significant at P=0.05 and P=0.01 levels respectively.

This suggested that parents might be presumed to have relatively greater number of favorable alleles for developing superior hybrids/varieties of pearl millet (Table 4). Out of 35 hybrids, three hybrids *viz.*, ICMA 07777 × 18488 R (9.53), ICMA 06777 × 18805 R (9.17) and ICMA 96222 × 18587 R (5.42) exhibited

Krishnan *et al* significant positive specific combining ability effects for grain yield per plant. Earlier significant GCA and SCA effects in pear millet for grain yield and component traits also reported by Jagendra Singh et al. [8], Patel et al. [12], Khandagale et al. [10], Priyanka [13] and Mungra et al [11].

Table 4: Top three ranking parent with respect to per se performance and gca effects and three top ranking hybrids with respect to per se performance and sca effects.

#### Krishnan et al

In general all characters of the crosses showing positive and negative combining ability effect, involved either good × good, average × good, good × poor, average × average, average × poor and poor × poor general combiners. Crosses between good × poor and poor × good combiners could be attributed to lack of co-adaptation between favourable alleles of the parents involved. Generally the cross showing high sca effects for grain yield per plant also exhibited high or average or poor sca effects for yield components (Table 4).

This indicated that yield is a complex dependent character which depends on a number of independent component characters.

## CONCLUSIONS

The cross ICMA 07777 × 18488 R showed significant positive specific combining ability effect and high sca effects involving one good general combiner, indicated additive × dominance type of interaction, which can produce desirable transgressive segregate in subsequent generations, also used for exploiting commercial cultivation. The cross ICMA 06777 × 18805 had good × average combiner parents, high *per se* performance and positive specific combining ability effect for grain yield per plant, test weight, ear head length and harvest index. The cross ICMA 96222 × 18488 R had good × good combiner parent, significant positive specific combining effect for grain yield per plant test weight and ear head length. This indicated to obtain desirable transgressive sergeants in  $F_2$  or subsequent generation, may be used for development of pollinated CMS line as female parent and pollen fertility restorer line as male parent for future breeding programme of grain yield per plant, production of high yielding hybrids and for commercial purpose.
